

Data Structure - Binary Search Tree

A Binary Search Tree (BST) is a tree in which all the nodes follow the below-mentioned properties –

- The value of the key of the left sub-tree is less than the value of its parent (root) node's key.
- The value of the key of the right sub-tree is greater than or equal to the value of its parent (root) node's key.

Thus, BST divides all its sub-trees into two segments; the left sub-tree and the right sub-tree and can be defined as –

$$\text{left_subtree (keys)} < \text{node (key)} \leq \text{right_subtree (keys)}$$

Representation

BST is a collection of nodes arranged in a way where they maintain BST properties. Each node has a key and an associated value. While searching, the desired key is compared to the keys in BST and if found, the associated value is retrieved.

Following is a pictorial representation of BST –

We observe that the root node key (27) has all less-valued keys on the left sub-tree and the higher valued keys on the right sub-tree.

Basic Operations

Following are the basic operations of a tree –

- **Search** – Searches an element in a tree.
- **Insert** – Inserts an element in a tree.

- **Pre-order Traversal** – Traverses a tree in a pre-order manner.
- **In-order Traversal** – Traverses a tree in an in-order manner.
- **Post-order Traversal** – Traverses a tree in a post-order manner.

Node

Define a node having some data, references to its left and right child nodes.

```
struct node {  
    int data;  
    struct node *leftChild;  
    struct node *rightChild;  
};
```

Search Operation

Whenever an element is to be searched, start searching from the root node. Then if the data is less than the key value, search for the element in the left subtree. Otherwise, search for the element in the right subtree. Follow the same algorithm for each node.

Algorithm

```
struct node* search(int data){  
    struct node *current = root;  
    printf("Visiting elements: ");  
  
    while(current->data != data){  
  
        if(current != NULL) {  
            printf("%d ", current->data);  
  
            //go to left tree  
            if(current->data > data){  
                current = current->leftChild;  
            } //else go to right tree  
            else {  
                current = current->rightChild;  
            }  
  
            //not found  
            if(current == NULL){  
                return NULL;  
            }  
        }  
    }  
}
```

```
    return current;
}
```

Insert Operation

Whenever an element is to be inserted, first locate its proper location. Start searching from the root node, then if the data is less than the key value, search for the empty location in the left subtree and insert the data. Otherwise, search for the empty location in the right subtree and insert the data.

Algorithm

```
void insert(int data) {
    struct node *tempNode = (struct node*) malloc(sizeof(struct node));
    struct node *current;
    struct node *parent;

    tempNode->data = data;
    tempNode->leftChild = NULL;
    tempNode->rightChild = NULL;

    //if tree is empty
    if(root == NULL) {
        root = tempNode;
    } else {
        current = root;
        parent = NULL;

        while(1) {
            parent = current;

            //go to left of the tree
            if(data < parent->data) {
                current = current->leftChild;
                //insert to the left

                if(current == NULL) {
                    parent->leftChild = tempNode;
                    return;
                }
            } //go to right of the tree
            else {
                current = current->rightChild;
```

```
//insert to the right
if(current == NULL) {
    parent->rightChild = tempNode;
    return;
}
}
```
